

# 15. MODULES

A module allows you to logically organize your Python code. Grouping related code into a module makes the code easier to understand and use. A module is a Python object with arbitrarily named attributes that you can bind and reference.

Simply, a module is a file consisting of Python code. A module can define functions, classes and variables. A module can also include runnable code.

## Example

The Python code for a module named *aname* normally resides in a file named *aname.py*. Here is an example of a simple module, *support.py*

```
def print_func( par ):  
    print "Hello : ", par  
    return
```

## The *import* Statement

You can use any Python source file as a module by executing an import statement in some other Python source file. The *import* has the following syntax:

```
import module1[, module2[,... moduleN]
```

When the interpreter encounters an import statement, it imports the module if the module is present in the search path. A search path is a list of directories that the interpreter searches before importing a module. For example, to import the module *hello.py*, you need to put the following command at the top of the script:

```
#!/usr/bin/python  
  
# Import module support  
import support  
  
# Now you can call defined function that module as follows
```
